Co₃O₄ catalysts supported on TiO₂ with different crystalline structures (anatase (A), rutile (R) and P25 (Degussa)) were prepared by a deposition-precipitation method, and characterized by nitrogen adsorption/desorption, XRD, HR-TEM, EPR, Raman spectroscopy, XPS and H₂-TPR techniques. The results show that Co₃O₄/TiO₂ (A) exhibited the highest activity among the three Co₃O₄/TiO₂ catalysts: CO can be completely oxidized to CO₂ at -43 °C. When rutile TiO₂ or P25 were used as the support, its catalytic activity was decreased obviously, because the TiO₂ crystal structure has an influence on the physicochemical and catalytic properties of the Co₃O₄ catalysts. The results show that the Co₃O₄/TiO₂ (A) catalyst contains Ti³⁺ species, which is in an unstable state and can affect the properties of Co₃O₄ by the interaction between the deposited Co₃O₄ and anatase TiO₂ support. The Co₃O₄/TiO₂ (A) catalyst exhibits highly defective structure and good oxygen adsorption ability. The reducibility of Co₃O₄ is improved by the anatase TiO₂ support, resulting in Co₃O₄/TiO₂ (A) possessing the better redox property than the other Co₃O₄/TiO₂ catalysts, which is an important factor for its high catalytic activity.

1. Introduction

Low-temperature oxidation of CO, as one of the most extensively studied reactions in the heterogeneous catalysis field, is becoming increasingly important in cleaning air and lowering automotive emissions.^{1,2} For the catalysts for CO oxidation, the precious metals (Pd, Pt and nano-Au) are well-known catalysts with high activity,³⁻⁶ but the reaction temperature of CO complete conversion over precious metals (such as Pt) is still pretty high and their stabilities are still poor. To overcome the high cost of precious metals, researchers try to design and develop the non-precious metal catalysts, such as the metal oxide catalysts. Among them, cobalt oxide (Co₃O₄) is thought to be a potential catalyst,⁷⁻¹⁰ because of its high activity for CO oxidation even at below 0 °C.^{11,12} Hence, Co₃O₄ catalysts for low-temperature CO oxidation are widely studied,^{10,13,14} including mix-valenced CoO_x,⁹ supported Co₃O₄,¹² noble metal (Au, Pt) supported on Co₃O₄,^{11,12} and Fe(or Ce)-doped Co₃O₄ catalyst,^{15,16} etc. These studies above for Co₃O₄ catalysts are mainly focused on the

preparation of Co₃O₄ and foreign element doping; for supported Co₃O₄ catalysts, their catalytic activities need still to be improved and the effects of structure and physicochemical properties of support on the catalytic performance of Co₃O₄ are less studied.

Titanium oxide (TiO₂) is extensively used in solid catalysts, particularly as a catalyst support.¹⁷⁻²⁰ When nano-metal particles are supported on TiO₂, there are often a strong metal-support interaction (SMSI).²¹ TiO₂ possesses multi-crystalline structures, and is mainly classified into anatase, rutile and brookite phases, among which anatase and rutile TiO₂ are generally used as engineering materials more frequently than the brookite phase TiO₂. As a photo-catalyst, TiO₂ crystalline phases can affect obviously its photo-catalytic activity.²²⁻²⁴ Palladium supported on anatase TiO₂ shows a higher activity than that on rutile TiO₂ for the selective hydrogenation of long chain alkadienes, due to the superior SMSI between Pd and anatase TiO₂.²⁵ Nanba *et al.*²⁶ studied the catalytic decomposition of acrylonitrile over Ag supported on TiO₂ with different crystal phases, and found that Ag/TiO₂ containing anatase TiO₂ exhibited higher NH₃ and N₂ selectivity at low and high temperatures, whereas Ag/TiO₂ with only rutile phase exhibited medium N₂ and higher NO_x selectivity at low and high temperatures. This may suggest that different crystalline phases of the TiO₂ support can affect the SMSI,¹⁸ electronic density, oxidation state, crystal

^b Research Institute of Applied Catalysis, Shanghai Institute of Technology, Shanghai 200235, PR China

size²⁰ and metal dispersion²⁷ of the deposited metal components. These changes in deposited metals (or metal oxides) supported on TiO₂ with different crystalline phases can have a dramatic impact on the catalytic performance.

Herein, we investigated mainly the effect of TiO₂ crystalline phases on the catalytic performance of Co₃O₄/TiO₂ for CO oxidation, as an approach to prepare a highly effective Co₃O₄/TiO₂ catalyst. Three kinds of TiO₂ with different crystalline structures were utilized as the supports of Co₃O₄ catalyst. We have found that Co₃O₄ supported on anatase TiO₂ (Co₃O₄/TiO₂ (A)) exhibits excellent catalytic activity and CO is completely converted at -43 °C. On the basis of the physicochemical properties of Co₃O₄/TiO₂ (A) obtained, the role of different crystalline phases of TiO₂ on promoting its catalytic activity was discussed.

2. Experimental section

2.1 Catalyst preparation

The TiO₂ supports used here are anatase phase (TiO₂ (A)), P25 and rutile phase (TiO₂ (R)) respectively. TiO₂ (A) (99.8% purity) and TiO₂ (R) (99.8% purity) were purchased from Aladdin industrial corporation. P25 contains both anatase and rutile phase and was purchased from Degussa Co.

The Co₃O₄/TiO₂ catalysts were prepared by a deposition-precipitation (DP) method. Weighed Co(NO₃)₂·6H₂O were dissolved in 100 ml de-ionized water at room temperature, and then 3 g TiO₂ (less than 100 mesh) were fully dispersed in the above solution. A sodium carbonate solution (1 M) was added to this suspension under continuous stirring until pH reached 10. This suspension was aged under stirring for 30 min and statically for 2 h, and then the precipitates were filtered, washed with de-ionized water several times, dried in air at 80 °C and calcined at 350 °C for 3 h in a muffle furnace. The synthesized catalysts are denoted as Co₃O₄/TiO₂ (A), Co₃O₄/TiO₂ (P25) and Co₃O₄/TiO₂ (R) according to the crystalline phase of the TiO₂ support. The metal oxide loading was 10 wt.% on the support.

2.2 Catalytic activity testing

The activities of the catalysts for CO oxidation were tested in a continuous flow quartz tube micro-reactor (Φ 8 mm \times 23 cm). 200 mg catalyst (40–60 mesh) was packed in the middle of the reactor. The flow rate of feed gas consisted of 1% CO, 10% O₂ and 89% N₂ was 20 ml min⁻¹. Before activity testing, the catalyst was pretreated in N₂ flow at 450 °C for 30 min and then cooled down to room temperature.

2.3 Characterization of catalysts

The BET surface areas of samples were measured by N₂ adsorption/desorption at -196 °C on a micromeritics ASAP-2020 instrument, and calculated by the Brunauer–Emmett–Teller (BET) method. Powder X-ray diffraction (XRD) patterns were recorded on a PANalytical PW 3040/60 X'Pert Pro powder diffractometer with CuK α radiation, which was operated at

40 kV and 40 mA and a scanning speed was 0.5° min⁻¹. High resolution transmission electron microscopy (HR-TEM) images were obtained on a JEOL JEM-2100 microscope operated at 200 kV, and the sample to be measured was first dispersed in ethanol and then collected on a copper grids covered with carbon film. After the liquid phase was evaporated the grid was loaded into the microscope. The EPR spectra were obtained on a Bruker EMX-8/2.7 EPR Spectrometer. Laser Raman spectra of samples were obtained on a Renishaw Raman spectrometer at ambient condition and the 514 nm line of a Spectra Physics Ar⁺ laser was used as an excitation. The laser beam intensity and the spectrum slit width were 2 mW and 3.5 cm⁻¹, respectively. X-ray photoelectron spectroscopy (XPS) spectra of samples were obtained on a Kratos Axis Ultra-DLD photoelectron spectrometer equipped with AlK α (1486.6 eV) radiation as the excitation source. All binding energies (BE) were determined with respect to the C 1s line (284.8 eV) originating from adventitious carbon.

H₂-Temperature programmed reduction (H₂-TPR) was performed in a quartz U-tube with 50 mg sample. After the sample was pretreated in N₂ at 450 °C for 30 min, it was cooled down to room temperature, and then the reduction gas of 10 vol.% H₂/N₂ (25 ml min⁻¹) was used instead of N₂. The heating rate was 10 °C min⁻¹. The uptake amounts of H₂ were measured by a thermal conductivity detector (TCD).

3. Results and discussion

3.1 Catalytic activity

The catalytic conversions of CO as a function of the reaction temperature over three catalysts under dry or moist conditions are shown in Fig. 1. The results show that three catalysts exhibit pretty good activity for CO oxidation under dry condition, and CO can be oxidized to CO₂ at ambient temperature. Among the three catalysts, Co₃O₄/TiO₂ (A) shows the best activity for CO oxidation, in which the reaction temperature of the CO complete conversion (T_{100}) is -43 °C. For the Co₃O₄/TiO₂ (P25) and Co₃O₄/TiO₂ (R) catalysts, their

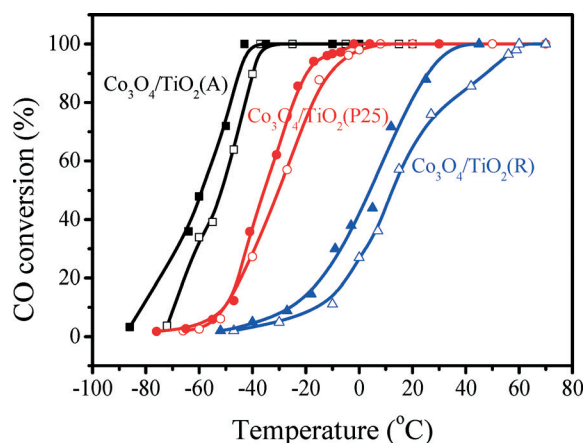

Fig. 1 The catalytic activities of Co₃O₄/TiO₂ catalyst (200 mg) for CO oxidation under dry condition (solid symbol) and 0.1% H₂O condition (hollow symbol).

T_{100} are increased to -2 °C and 45 °C respectively. Under moist condition (0.1% H_2O), the activities of the three catalysts are decreased, their T_{50} (the reaction temperature for 50% CO conversion) are raised by $6-8$ °C. The reason is that water might occupy the active sites of cobalt oxide, resulting in a deactivation of the catalyst.

The stabilities of the catalysts under dry or moist condition were also tested at 15 °C. As the results in Fig. 2 show, the stability of Co_3O_4/TiO_2 (A) is the best among the three catalysts, its CO conversion can be maintained at 100% after 180 min of reaction under dry condition, and then its activity is decreased. Under moist condition, because of the poison effect of water, the activity of Co_3O_4/TiO_2 (A) is decreased much faster than that under dry condition. As for Co_3O_4/TiO_2 (P25) and Co_3O_4/TiO_2 (R), their activities are decreased as the reaction begins, and totally lost after 60 min of reaction, regardless under which (dry or moist) condition.

Even so, the results above (Fig. 1 and 2) indicate that the crystalline phase of TiO_2 support has an obvious influence on the performance of the Co_3O_4/TiO_2 catalyst for CO oxidation. As Co_3O_4/TiO_2 (R) deactivates more early than other two samples, its light-off curve shows the shallower slope than that of the other two samples, because a deactivation of the active sites on Co_3O_4/TiO_2 (R) has taken place ceaselessly when the reaction temperature rose.

3.2 N_2 adsorption-desorption and XRD

With the help of low-temperature N_2 adsorption, the BET surface areas (S_{BET}) of Co_3O_4/TiO_2 (A), Co_3O_4/TiO_2 (P25) and Co_3O_4/TiO_2 (R) were measured, and found to be 91.8 $m^2 g^{-1}$, 48.7 $m^2 g^{-1}$ and 38.0 $m^2 g^{-1}$, respectively. These results illustrate that Co_3O_4 supported on the anatase TiO_2 possesses a larger BET surface area than the other two catalysts, which may be one of the reasons for its high catalytic activity for CO oxidation.

The XRD patterns of the three TiO_2 supports and three Co_3O_4/TiO_2 catalysts are shown in Fig. 3. The characteristic

Fig. 2 The long-term stabilities of Co_3O_4/TiO_2 catalysts for CO oxidation under dry condition (solid symbol) and 0.1% H_2O condition (hollow symbol) at 15 °C.

diffraction peaks of anatase TiO_2 were detected at $2\theta = 25.4^\circ$ (101), 37.9° (004) and 48.1° (200), and the diffraction peaks of rutile TiO_2 are located at $2\theta = 27.5^\circ$ (110), 36.1° (101) and 54.4° (211). The crystallite sizes of the supports were calculated by Scherrer's equation²⁸ and shown in Table 1. The results show that the crystallite size of TiO_2 (R) > TiO_2 (P25) > TiO_2 (A). In the XRD patterns of Co_3O_4 supported on different supports, the characteristic XRD peaks of Co_3O_4 cannot be observed, indicating that Co_3O_4 particles highly dispersed on the support or its particles are too small to be detected by XRD.

3.3 High-resolution transmission electron microscopy (HR-TEM)

Representative HR-TEM images of Co_3O_4/TiO_2 (A), Co_3O_4/TiO_2 (P25) and Co_3O_4/TiO_2 (R) catalysts are shown in Fig. 4. The crystallite sizes of the three catalysts are $10-30$ nm and the rank of the crystallite size is Co_3O_4/TiO_2 (A) > Co_3O_4/TiO_2 (P25) > Co_3O_4/TiO_2 (R), which is in agreement with the calculated results by Scherrer formula on the basis of the X-ray diffraction peak broadening. It is difficult to distinguish Co_3O_4 from TiO_2 in the TEM images. In the HR-TEM image (Fig. 4B), Co_3O_4 crystallites can be observed by the help of the ordered fingerprints with the space distance (0.243 nm) between (311) facets in the crystalline Co_3O_4 (in white rectangle). The TiO_2 crystallites which were shown in the white circle can be distinguished by the space distance (0.352 nm) between (101) facets in the crystalline anatase TiO_2 .

3.4 Electron paramagnetic resonance (EPR)

EPR is a useful technique for obtaining information on the electronic structure of solid catalysts. The EPR spectra of Co_3O_4/TiO_2 catalysts are shown in Fig. 5A, and that of TiO_2

Fig. 3 XRD patterns of the Co_3O_4/TiO_2 catalysts and the TiO_2 supports.

Table 1 The BET surface area (S_{BET}), crystal size and T_{100} values of the catalysts

Catalyst	S_{BET} ($m^2 g^{-1}$)	Crystal size (nm)	T_{100} (°C)
Co_3O_4/TiO_2 (A)	91.8	15.60	-43
Co_3O_4/TiO_2 (P25)	48.7	20.02 (A), 20.39 (R)	-2
Co_3O_4/TiO_2 (R)	38.0	22.88	45

Fig. 4 HR-TEM images of (A and B) $\text{Co}_3\text{O}_4/\text{TiO}_2$ (A), (C) $\text{Co}_3\text{O}_4/\text{TiO}_2$ (P25) and (D) $\text{Co}_3\text{O}_4/\text{TiO}_2$ (R) catalysts.

supports are shown in Fig. 5B. The signals of g values less than 2 were assigned to Ti^{3+} ($3d^1$).^{17,29,30} Ti^{3+} species are produced by the trapping of electrons at defective sites in TiO_2 .³¹ The signals for $g_{\perp} = 1.996$ and $g_{\parallel} = 1.966$ can be attributed to electrons trapped in Ti^{3+} sites.^{25,32} As can be observed, the EPR signal of Ti^{3+} can be found on $\text{Co}_3\text{O}_4/\text{TiO}_2$ (A) and TiO_2 (A) support, and their EPR spectra are almost the same, indicating that Ti^{3+} exists in TiO_2 (A) and after Co_3O_4 loading it still maintained. Comparing with $\text{Co}_3\text{O}_4/\text{TiO}_2$ (A),

and the Ti^{3+} signals on $\text{Co}_3\text{O}_4/\text{TiO}_2$ (P25) and $\text{Co}_3\text{O}_4/\text{TiO}_2$ (R) are weakened and broadened, which are contributed to the formation of diamagnetically coupled Ti^{3+} pairs or the coupling of no-diamagnetic Ti^{3+} ions.³³ For TiO_2 (R), its EPR signal is obviously increased after Co_3O_4 loading, and Ti^{3+} ions in $\text{Co}_3\text{O}_4/\text{TiO}_2$ (R) tend to coupling. As for TiO_2 (P25) or $\text{Co}_3\text{O}_4/\text{TiO}_2$ (P25), both the EPR signals are very weak and broad, which can be attributed to the structure complexity of the catalyst or a mixture of anatase and rutile TiO_2 .

It was reported that the g values in the EPR spectra of TiO_2 are usually below 2.1,^{29–34} and a resonance at $g = 1.979$ is characteristic of electrons trapped in tetrahedral Ti^{4+} sites in rutile TiO_2 .³⁴ In the EPR spectrum of $\text{Co}_3\text{O}_4/\text{TiO}_2$ (R), the signal at $g = 2.019$ is probably caused by the interaction between Co_3O_4 and TiO_2 (R), and the resonance at $g = 2.278$ is caused by the widening of the peak, relating to the relaxation time of spin transition. The formation of Ti^{3+} ions can be assumed to represent an unstable state, which can have a significant influence on the crystalline and interfacial region of TiO_2 between deposited Co_3O_4 and TiO_2 support. The strong signal of Ti^{3+} in $\text{Co}_3\text{O}_4/\text{TiO}_2$ (A) indicates that the catalyst contains a defective structure, which promotes the catalytic performance of $\text{Co}_3\text{O}_4/\text{TiO}_2$ (A) for CO oxidation.

3.5 Laser Raman spectroscopy

Fig. 6 shows the laser Raman spectra of the TiO_2 supports and $\text{Co}_3\text{O}_4/\text{TiO}_2$ catalysts. The results show that the vibration bands of anatase TiO_2 are located at 142, 197, 396, 516, and 639 cm^{-1} ,^{35–37} and the vibration bands of rutile TiO_2 are located at 236, 447, and 610 cm^{-1} .^{38,39} In the Raman spectrum of TiO_2 (P25), there are the vibration bands of anatase and rutile TiO_2 . After Co_3O_4 loading, the Raman vibration bands of TiO_2 are broadened, which may be attributed to an interaction of TiO_2 with cobalt species and disorder in the oxygen sublattice.⁴⁰ It was reported that there are some vibration bands at 193, 475, 516, 615, and 680 cm^{-1} in the Raman spectra of Co_3O_4 ,^{35–37,41} in which the band around 680 cm^{-1} is attributed to the A_{1g} symmetry.⁴² The vibration band of A_{1g} on $\text{Co}_3\text{O}_4/\text{TiO}_2$ (A) appeared at 679 cm^{-1} , the lowest wavenumber among the three catalysts, which is a sensitive

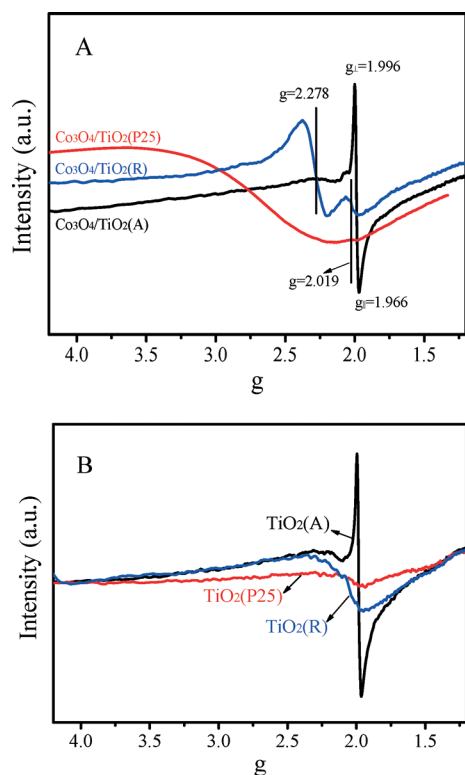

Fig. 5 EPR spectra of the $\text{Co}_3\text{O}_4/\text{TiO}_2$ catalysts (A) and the TiO_2 supports (B).

Fig. 6 Laser Raman spectra of the synthesized catalysts and supports.

indication for the highly defective structure.⁴³ The defective structure is known to play crucial role in the CO oxidation,⁴⁴ which may be related to its high catalytic activity. For the Co₃O₄/TiO₂ (P25) catalyst, there are two bands of Co₃O₄ at 475 and 682 cm⁻¹.

3.6 X-ray photoelectron spectroscopy (XPS)

The surface properties of the supported catalysts were further explored by XPS, and the peak-fitting Co 2p XPS spectra of three catalysts are shown in Fig. 7. It was reported that the binding energies of Co³⁺ and Co²⁺ ions are 780.2 ± 0.6 and 781.8 ± 0.6 eV, respectively,⁴⁵ and the energy difference between the Co 2p_{3/2} peak and the Co 2p_{1/2} peak is approximately 15 eV. Two small peaks at 786.3 eV and 804.8 eV are the shake-up satellite peaks of Co²⁺. The binding energies of Co 2p_{3/2} and Co 2p_{1/2} of the Co₃O₄/TiO₂ catalysts were summarized in Table 2. The results show that the binding energies of Co 2p in the spectra of Co₃O₄/TiO₂ (A) and Co₃O₄/TiO₂ (P25) are smaller than that of Co₃O₄/TiO₂ (R), indicating that the electron binding ability of Co ions in the Co₃O₄/TiO₂ (R) catalyst is bigger than that in the other two catalysts and the structure nature of TiO₂ support affects the electron transfer ability of Co ions on the TiO₂ support. In addition, we can find that the peak area of Co₃O₄/TiO₂ (R) is the highest among the three catalysts, which might be caused by the lowest surface area of TiO₂ (R). As the Co₃O₄ loading is the same for the three catalysts, the smaller surface area makes the concentration of Co relatively higher.

Fig. 8 shows the O 1s XPS spectra of the three catalysts. The O 1s peak can be fitted to three kinds of Gaussian peaks.

The peak at 529.0–530.2 eV (binding energy) should be assigned to surface lattice oxygen (O_{lat}), the peak at 530.3–531.1 eV can be assigned to adsorbed oxygen (O_{ads}, O⁻, O₂⁻ or O₂²⁻) species, and the peak at 531.6–532.5 eV is commonly ascribed to adsorbed H₂O or surface carbonate.^{46–48} The adsorbed oxygen species of O⁻ and O₂⁻ are known to be active for oxygen exchange and CO oxidation.^{49–51} The results in Fig. 8 show that the O_{ads} peak gradually shifted to higher binding energy from Co₃O₄/TiO₂ (A) to Co₃O₄/TiO₂ (R), indicating that the electronic density of oxygen is decreased, which may be attributed to the contribution of surface hydroxyl groups bounded to the cobalt or titanium ions. The peak of surface hydroxyl and carbonate on Co₃O₄/TiO₂ (R) is much stronger than that on the other two catalysts, resulting in blocking of the active sites for CO adsorption, which is usually considered as a deactivation reason of the catalysts for CO oxidation.^{52,53} Therefore, the surface of Co₃O₄/TiO₂ (R) is easily covered by carbonate and hydroxyl groups, resulting in a decrease in its catalytic activity, which can be further verified by the O 1s peak of surface carbonate at 532.4 eV. The ratios of O_{ads}/O_{lat} in Table 2 show that Co₃O₄/TiO₂ (A) with O_{ads}/O_{lat} = 0.58 exhibits the highest activity, and Co₃O₄/TiO₂ (A) with O_{ads}/O_{lat} = 0.72 shows the lowest activity, which should be ascribed to the presence of carbonates on Co₃O₄/TiO₂ (A) to inhibit adsorption of CO on the catalyst surface. The results above show that a relatively clean surface with more adsorbed oxygen is beneficial to improve the catalytic activity of the Co₃O₄/TiO₂ catalyst for CO oxidation.

In the Ti 2p XPS spectra in Fig. 9, the peaks of Ti 2p_{3/2} and Ti 2p_{1/2} are located at 458.6 and 464.4 eV respectively,

Fig. 7 The Co 2p XPS spectra of Co₃O₄/TiO₂ catalysts.

Fig. 8 The O 1s XPS spectra of Co₃O₄/TiO₂ catalysts.

Table 2 XPS data binding energies of Co 2p_{3/2}, Co 2p_{1/2} and O 1s, O_{ads}/O_{lat} of Co₃O₄/TiO₂ (A), Co₃O₄/TiO₂ (P25) and Co₃O₄/TiO₂ (R)

Catalyst	Co 2p _{3/2} (eV)	Co 2p _{1/2} (eV)	O 1s (eV)	O _{ads} /O _{lat}	Ti 2p _{3/2} (eV)	Ti 2p _{1/2} (eV)
Co ₃ O ₄ /TiO ₂ (A)	779.8	794.9	529.7	0.58	458.6	464.4
	781.4	796.6	530.3			
			531.6			
Co ₃ O ₄ /TiO ₂ (P25)	779.6	794.7	529.9	0.49	458.9	464.7
	781.2	796.4	530.5			
			531.8			
Co ₃ O ₄ /TiO ₂ (R)	780.8	795.9	530.2	0.72	458.9	464.7
	782.5	797.7	531.1			
			532.4			

which agree well with the values reported.⁵⁴ As can be observed, the peak intensity of $\text{Co}_3\text{O}_4/\text{TiO}_2$ (R) is much lower than that of the other two catalysts, which may be caused by its lower surface area. The Ti 2p peaks of $\text{Co}_3\text{O}_4/\text{TiO}_2$ (P25) and $\text{Co}_3\text{O}_4/\text{TiO}_2$ (R) shift to higher binding energy than $\text{Co}_3\text{O}_4/\text{TiO}_2$ (A), indicating that Ti ions in $\text{Co}_3\text{O}_4/\text{TiO}_2$ (P25) and $\text{Co}_3\text{O}_4/\text{TiO}_2$ (R) possess a higher valence state than that in $\text{Co}_3\text{O}_4/\text{TiO}_2$ (A). The binding energies of Ti 2p are listed in Table 2.

3.7. H_2 -TPR

The H_2 -TPR profiles of the $\text{Co}_3\text{O}_4/\text{TiO}_2$ catalysts and TiO_2 supports are shown in Fig. 10. The results show that the TiO_2 supports exhibit weak reduction peaks, so that the reduction peaks of the $\text{Co}_3\text{O}_4/\text{TiO}_2$ catalysts mainly result from the reduction of Co_3O_4 . $\text{Co}_3\text{O}_4/\text{TiO}_2$ (A) exhibit two reduction peaks at ~ 297 °C and 445 °C. The peak at 200–350 °C may be attributed to the reduction of Co^{3+} to Co^{2+} , and the peak at 350–700 °C can be attributed to the reduction of Co^{2+} to Co^0 .^{55,56} For the $\text{Co}_3\text{O}_4/\text{TiO}_2$ (P25) catalyst, its TPR reduction peaks are similar to that of the $\text{Co}_3\text{O}_4/\text{TiO}_2$ (A) catalyst, except for the small peak at 325 °C. However, the reason for the reduction peak formation at 325 °C is unclear, and it may be the reduction of Co^{3+} at the interfacial region between anatase and rutile TiO_2 . Unlike the TPR curves of $\text{Co}_3\text{O}_4/\text{TiO}_2$ (A) and $\text{Co}_3\text{O}_4/\text{TiO}_2$ (P25), the high-temperature reduction peak of $\text{Co}_3\text{O}_4/\text{TiO}_2$ (R) shifts ~ 575 °C. Thus Co^{2+} on anatase TiO_2 is

Fig. 9 The Ti 2p XPS spectra of $\text{Co}_3\text{O}_4/\text{TiO}_2$ catalysts.

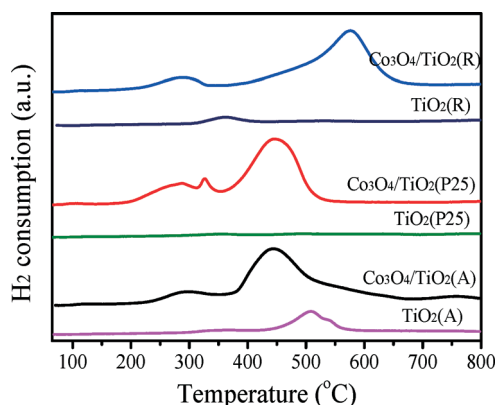

Fig. 10 H_2 -TPR profiles of the $\text{Co}_3\text{O}_4/\text{TiO}_2$ catalysts and TiO_2 supports.

easily reduced compared with Co^{2+} on rutile TiO_2 . That is to say, the reducibility of Co_3O_4 (special for Co^{2+}) is obviously affected by the structure of the TiO_2 support. Anatase TiO_2 supported Co_3O_4 catalysts show the best reducibility, which results probably in its high catalytic performance for CO oxidation.

3.8. Discussion

For supported catalysts, the type of support often plays a crucial role in the performance of the catalysts with the help of an interaction between the active components and the support. TiO_2 has three main crystalline structures: anatase (tetragonal $I4/am\bar{d}$), brookite (orthorhombic $Pcab$), and rutile (tetragonal $P42/mnm$), and anatase and rutile are usually used as catalyst supports, among them, anatase tends to be more stable at low temperature and rutile is the stable form at higher temperature. And the reactivity of anatase is higher than rutile. Nanba *et al.*²⁶ found that the TiO_2 crystal phase could affect the oxidation state of Ag supported on TiO_2 catalyst for acrylonitrile decomposition, that is Ag particles on anatase TiO_2 was of an oxidized state and that on rutile was metallic. Kang *et al.*⁵⁷ investigated CO oxidation over CuO/TiO_2 , and found that CuO dispersion, an interaction between CuO and TiO_2 and the oxidation state of copper component were changed by the crystal structure of the TiO_2 support, and the catalytic activity of the catalyst supported on rutile TiO_2 was the highest. For different reactions with different catalysts, the effect of the crystal phase of TiO_2 on the catalytic performance might not be the same. Herein, the CO oxidation over $\text{Co}_3\text{O}_4/\text{TiO}_2$ was investigated, and the effect of the crystal phase of TiO_2 on the catalytic performance of Co_3O_4 catalyst was discussed.

The $\text{Co}_3\text{O}_4/\text{TiO}_2$ (A) catalyst exhibits higher activity and better stability for CO oxidation than $\text{Co}_3\text{O}_4/\text{TiO}_2$ (P25) and $\text{Co}_3\text{O}_4/\text{TiO}_2$ (R) (Fig. 1 and 2), which may be attributed to the following reasons. (1) The $\text{Co}_3\text{O}_4/\text{TiO}_2$ (A) catalyst possesses a higher BET surface area and smaller crystalline size than the other two catalysts. As the diffraction peaks of Co_3O_4 cannot be detected in the XRD profiles (Fig. 3), Co_3O_4 is highly dispersed on the TiO_2 support and interacts closely with the support. (2) The EPR results (Fig. 5) indicate that Ti^{3+} species only exists in $\text{Co}_3\text{O}_4/\text{TiO}_2$ (A), which is in an unstable state and has a significant influence on the catalytic property of the catalyst. (3) In the Raman spectra (Fig. 6), the A_{1g} peak of Co_3O_4 shifted to lower wavenumber when anatase TiO_2 was used as the support, which illustrates a highly defective structure for $\text{Co}_3\text{O}_4/\text{TiO}_2$ (A) and plays a crucial role in the CO oxidation. (4) The electron transfer ability of Co ions was enhanced by the help of the anatase TiO_2 support, resulting in a good oxygen adsorption ability of $\text{Co}_3\text{O}_4/\text{TiO}_2$ (A) by means of the clean surface, which were verified by the XPS results (Fig. 7 and 8). (5) The H_2 reduction behaviour of Co_3O_4 is improved due to the presence of the anatase TiO_2 support (Fig. 10), unlike $\text{Co}_3\text{O}_4/\text{TiO}_2$ (R) and $\text{Co}_3\text{O}_4/\text{TiO}_2$ (P25).

The results above show that the physicochemical properties of Co_3O_4 can be varied by the crystal structure of the

TiO₂ support. The presence of Ti³⁺ ions in Co₃O₄/TiO₂ (A) as a defective structure, is in favour of forming oxygen vacancies,⁵⁸ which was observed in Raman spectra (Fig. 6). The oxygen vacancies can adsorb oxygen from the gas phase and weaken its bond to form the activated oxygen species.⁵⁹ The activated oxygen species could accelerate the oxygen exchange and surface diffusion to promote the catalytic oxidation of CO. In other words, the defective structure can accelerate the oxygen exchange and surface diffusion to prevent the formation of carbonate species and slow down the accumulation of carbonate species, resulting in an increase in the catalytic activity for CO oxidation, which was verified by the O 1s XPS spectra (Fig. 8), because the accumulation of carbonate species on the surface would lead to the decrease of the catalytic activity for CO oxidation.^{52,53}

Furthermore, the reducibility of Co₃O₄ is also affected by the crystalline structure of the TiO₂ support, and the reduction temperature of Co₃O₄/TiO₂ (A) is lower compared with the other two catalysts. In the process of CO oxidation, the reduction of Co ions is a very important step in the redox catalytic cycle, which plays a crucial role in the CO oxidation.

4. Conclusions

Highly dispersed Co₃O₄ nanoparticles supported on three types of TiO₂ with different crystalline structures (anatase phase TiO₂ (A), P25 (Degussa) and rutile phase TiO₂ (R)) were prepared by a deposition–precipitation method. The results show that the crystalline structure of TiO₂ would affect obviously the physicochemical and catalytic properties of the Co₃O₄/TiO₂ catalysts, and the Co₃O₄/TiO₂ (A) catalyst exhibits the highest activity for CO oxidation among the three Co₃O₄/TiO₂ catalysts. The excellent catalytic performance of the Co₃O₄/TiO₂ (A) catalyst for CO oxidation can be attributed to the following reasons:

(1) The Co₃O₄/TiO₂ (A) catalyst possesses a higher BET surface area and smaller crystalline size than Co₃O₄/TiO₂ (P25) and Co₃O₄/TiO₂ (R); and Co₃O₄ is highly dispersed on the TiO₂ support and interacts closely with the support.

(2) The Ti³⁺ species exists in Co₃O₄/TiO₂ (A), which is in an unstable state and has a significant influence on the catalytic property of the catalyst. Furthermore Co₃O₄/TiO₂ (A) exhibits a highly defective structure that plays a crucial role in the CO oxidation.

(3) The electron transfer ability of Co ions was enhanced by the help of the anatase TiO₂ support, resulting in a good oxygen adsorption ability of Co₃O₄/TiO₂ (A) by means of the clean surface. The reducibility of Co₃O₄ is improved due to the presence of the anatase TiO₂ support, so that Co₃O₄/TiO₂ (A) possesses the best redox property among the three Co₃O₄/TiO₂ catalysts.
